Probability is starting with an animal, and figuring out what footprints it will make. Statistics is seeing a footprint, and guessing the animal. Probability is straightforward: you have the bear. Measure the foot size, the leg length, and you can deduce the footprints.

As you already know, statistics is the application of the laws of probability to real, actual data. If you take the D20 example, this would be when you roll the dice 20 times and collect some data. When you apply probability to real data, you are trying to determine if the outcome is significantly different from a model that you are generating.

A probability of one represents certainty: if you flip a coin, the probability you'll get heads or tails is one (assuming it can't land on the rim, fall into a black hole, or some such). The probability of getting a given number of heads from four flips is, then, simply the number of ways that number of heads can occur, divided by the number of total results of four flips, 16.
